

Create Virtual Hosts

First read this <http://tomcat.apache.org/tomcat-7.0-doc/config/host.html>

If you want tomcat to accept requests for different hosts e.g., `www.myhostname.com` then you must

0. create `${catalina.base}/www/appBase`, `${catalina.base}/www/deploy`, and `${catalina.base}/conf/Catalina/www.myhostname.com`

1. add a host entry in the `server.xml` file

```
<Host appBase="www/appBase" name="www.myhostname.com" />
```

2. Create the the following file under `conf/Catalina/www.myhostname.com/ROOT.xml`

```
<?xml version="1.0" encoding="UTF-8"?>
<Context docBase="${catalina.base}/www/deploy/mywebapp.war">
</Context>
```

Add any parameters specific to this hosts webapp to this context file

3. put your war file in `${catalina.base}/www/deploy`

When tomcat starts, it finds the host entry, then looks for any context files and will start any apps with a context.

To add more sites just repeat and rinse, all webapps can share the same war file location and appbase.
