

Redirects

A [Pipeline](#) can both forward requests internally (to another pipeline) or send explicit redirects back to the client.

The `redirect-to` element must have one of these 2 attributes:

- `resource` – the resource to forward to
- `uri` – the URI to redirect to.

With the `resource` attribute set, pipeline processing continues with the named resource. In recent releases (2.1.1 and later - I haven't looked at earlier versions), this is deprecated in favour of `call`.

```
<map:call resource="something"/>
```

With a `uri` attribute, a HTTP redirect response is send to the client. The pipeline processing ends. In this case, three Boolean parameters may be set. They all default to `false`.

- `global` – ???
- `permanent` – set `true` to make the HTTP redirect permanent
- `session` – indicates whether the session should be maintained during the redirect

```
<map:redirect-to uri="http://google.com/" />
```
